Abstract

Background: Algeria is experiencing a nutritional transition and increasing overweight in children.

Aims: This study aimed to determine the prevalence of overweight and underweight in children aged 6–10 years in Constantine city, Algeria using four international reference cut-offs for body mass index.

Methods: A cross-sectional study was conducted between February and May 2015 with a sample of 509 schoolchildren aged 6–10 years. Height and weight were measured according to World Health Organization (WHO) recommendations. The body mass index cut-offs of WHO, International Obesity Task Force, Centers for Disease Control and Prevention (CDC) and French national references were used to classify the sample as underweight and overweight according to age and sex. The kappa coefficient was used to assess agreement between the reference cut-offs.

Results: Based on the of different reference cut-offs, the prevalence of underweight in the children varied from 1.4% to 8.8%. The prevalence of overweight varied from 22.8% to 28.3%. The WHO cut-off gave a significantly higher prevalence of overweight in boys than girls (32.6% versus 24.0%, $P = 0.03$). The kappa values (between 0.251 and 0.954) indicated a fair to excellent agreement between the different reference cut-offs.

Conclusion: The prevalence of overweight and underweight differs in the Constantine children depending on the reference cut-off used, suggesting international references should be used with care to avoid potential misclassification of children's nutritional status.

Introduction

Overweight is increasing in children worldwide while underweight is decreasing in many countries. Among children in developing countries, underweight is still a greater problem than overweight. However, many countries have experienced a rising trend in the prevalence of overweight children (1,2). This shift is attributed to marked changes in lifestyles including increased sedentary behaviour and the introduction of westernized poor-quality diets and drinks. This nutritional transition is underway, at varying rates, in most developing countries, including Algeria.

In Algeria, we do not have representative nationwide studies on the prevalence of overweight and obese children older than 5 years. Local studies conducted in some regions do not allow defining the nationwide prevalence. However, they raise awareness that overweight and obesity in children in Algeria is increasing and could become a real public health problem. In Constantine, based on a sample of 19 263 children aged 6–10 years, the prevalence of overweight including obesity increased from 6.8% in 2001 to 9.5% in 2006 and the prevalence of underweight decreased from 34.3% to 24.5% (3).

Body mass index (BMI) is used extensively to measure malnutrition. Various international BMI reference cut-offs are available to determine the prevalence of malnutrition, particularly overweight and underweight in children. These include reference cut-off points of the International Obesity Task Force (IOTF) (4), the United States Centers for Disease Control and Prevention (CDC 2000) (5), French reference cut-off points published in 1982 and revised in 1991 (6), and the World Health Organisation (WHO), 2007 (7) and IOTF-2007 (8).

Our study aimed to determine the prevalence of overweight including obesity and underweight in a sample of children aged 6–10 years living in Constantine city using different international reference cut-off points for BMI to allow comparison between different studies and countries.

Methods

Study setting

The study was conducted in the city of Constantine, which is the capital of the province of Constantine (in the north-east of Algeria). Constantine is located 439 km

from Algiers, the capital of Algeria. It is the third largest city of Algeria in terms of population. In the last census of 2008 (9), the resident population of the city of Constantine was 448 374. The population of children aged 6–10 years was 32 937.

Study sample

This cross-sectional study was conducted between February and May 2015, and covered a sample of 509 children (254 girls and 255 boys) aged 6–10 years attending primary schools in the city of Constantine. Four schools were selected. These schools were chosen for their location in different geographical areas of Constantine. We could not assess other schools as we did not have permission from the Primary Education Department of Constantine to include more schools. In Algeria, school education is free and obligatory, so children of all social categories are present. All children aged 6–10 years attending these four schools were chosen.

BMI criteria

Height and weight were measured according to WHO recommendations (10) by a trained student. The body weight (in kilograms) was measured to the nearest 0.1 kg using regularly calibrated electronic scales (Seca, Germany). Height was measured in a standing position without shoes to the nearest 0.1 cm using a stadiometer (Seca, Germany). BMI was calculated as weight (kg) divided by height squared (m^2). The 2007 WHO reference cut-off is based on the sample used to construct the original charts of the American Department of Health, Education and Welfare (11). The 2007 WHO reference allows unrestricted calculation of BMI centiles and z-score curves on a continuous age scale from 5 to 19 years. A score of > 1 standard deviation (SD) is considered the overweight cut-off point, a score of < -2 SD is considered the underweight cut-off point (7). The IOTF reference has published a series of sex- and age-specific BMI cut-offs (from 6 to 18 years) which were developed from sex-specific BMI age curves that pass through a BMI of 25 kg/m^2 for overweight and 30 kg/m^2 for obesity at age 18 years (4). For the detection of underweight, IOTF constructed reference cut-offs based on the WHO definition of underweight for adults (8). The CDC 2000 reference is the revised version of the 1977 (American) National Center for Health Statistics growth charts. Here, the 85th centile is considered the cut-off for overweight and the 5th centile the cut-off for underweight (5). According to the French reference published in 1982 and revised in 1991, underweight and overweight are defined as < 3 rd centile and > 97 th centile respectively (6).

Statistical analysis

Statistical analysis was done using Statview software, version 5 (Abacus ConceptsTM, Berkeley, USA). Data were analysed using the chi-squared and Student t-tests to assess differences by age and sex. The kappa coefficient was used to assess the inter-variation between the references. A kappa value > 0.4 was considered moderate

agreement, and a value > 0.75 was considered good agreement (12). The significance level was set at $P < 0.05$.

Results

The mean BMI of the children according to age and sex increased with age between 6 and 10 years with no statistically significant difference by sex (Table 1).

Table 2 shows the prevalence of underweight and overweight by age of the children. The four reference cut-offs all indicated a low prevalence of underweight. The IOTF cut-off showed the highest prevalence of underweight in all age. The new reference cut-off of WHO showed no underweight in children younger than 8 years. For overweight, the French reference indicated a comparatively low prevalence of overweight compared with the other reference cut-offs. The WHO reference showed the highest prevalence of overweight in all ages.

The prevalence of underweight and overweight by age and sex according to various references are presented in Table 3. The overall prevalence of overweight as determined by IOTF and French cut-offs followed a similar trend in both sexes. IOTF and French references classified 21.3% and 18.9% of the girls and 24.3% and 22.0% of the boys, respectively, as overweight. The WHO reference showed a significantly higher prevalence of overweight in boys than girls (32.6% versus 24.0%, $P = 0.03$). This was because 39.6% of 7-year-old boys were classified as overweight with the WHO reference cut-off compared with 18.8% of 7-year-old girls ($P = 0.01$) as were 43.2% of 10-year-old boys compared with 22.6% of 10-year-old girls ($P = 0.03$). The prevalence of overweight according to the CDC reference cut-offs was much higher in boys compared with girls, even though overall the difference was not statistically significant (26.3% versus 19.3%, $P = 0.06$). However, the CDC reference cut-offs showed a significantly higher prevalence of overweight in 7-year-old boys than in girls (37.5% versus 17.4% respectively, $P = 0.01$). The IOTF reference shows the highest prevalence of underweight for girls (10.6%) and boys (7.1%).

The kappa coefficients comparing overweight and underweight between the different reference cut-offs are presented in Table 4. With regard of the detection of underweight, the kappa coefficient values (boys = 0.89, girls = 0.95) suggest an excellent agreement between

Table 1 Mean body mass index of the children by age and sex

Age (years)	Mean body mass index (SD)		P-value
	Girls	Boys	
6	23.47 (3.44)	24.28 (4.80)	0.33
7	25.75 (5.15)	27.41 (5.55)	0.09
8	31.46 (9.37)	29.58 (6.73)	0.24
9	32.66 (7.58)	33.94 (8.57)	0.47
10	36.38 (8.99)	38.98 (9.04)	0.16

SD: standard deviation.

Table 2 Prevalence of underweight and overweight in the children by age according to the international reference cut-offs

Variable	Prevalence (%)					
	6 years (n = 111)	7 years (n = 117)	8 years (n = 101)	9 years (n = 83)	10 years (n = 97)	Total (n = 509)
Underweight						
WHO	0.0	0.0	2.0	2.4	3.1	1.4
IOTF	9.0	11.1	4.9	8.4	10.3	8.8
CDC	2.7	2.6	3.0	2.4	6.2	3.3
French reference	1.8	1.7	2.0	2.4	3.1	2.2
Overweight						
WHO	28.8	27.3	27.7	25.3	31.9	28.3
IOTF	23.4	22.2	23.8	20.5	23.7	22.8
CDC	23.4	25.6	22.8	19.3	21.6	22.8
French reference	20.7	17.9	19.8	20.5	23.7	20.4

WHO: World Health Organization, IOTF: International Obesity Task Force, CDC: Centers for Disease Control and Prevention.

WHO and French references for both sexes ($\kappa = 0.77$). An excellent agreement was also found between the French and CDC references (boys, $\kappa = 0.91$ and girls, $\kappa = 0.93$). However, the kappa values show very low agreement for boys between IOTF and WHO reference cut-offs ($\kappa = 0.35$), IOTF and CDC ($\kappa = 0.48$) and IOTF and French ($\kappa = 0.42$).

In terms of overweight, in girls, an excellent agreement between all references was found (κ between 0.76 and 0.94). For boys, an excellent agreement was found between WHO and CDC references ($\kappa = 0.85$) and between IOTF and CDC ($\kappa = 0.95$) and IOTF and French references ($\kappa = 0.93$).

Discussion

In our sample, the prevalence of underweight using different reference cut-offs varied from 1.4% to 8.8%.

This prevalence is lower than that observed in India (13) and Morocco (14) but close to that found in Algeria (Si-di-bel-Abbes) in 2008 (15).

Few studies have reported the prevalence of obesity, which has reached epidemic proportions among children in developing countries (16,17). Using the CDC and IOTF reference cut-offs, 22.8% of our sample of children were overweight. This prevalence is considerably lower than that found in Saudi Arabia (40.6%) (18), Libya (45%) (19), Abu Dhabi (33.6%) (20), Egypt (31.2%) (21) and South Africa (30.7%) (22). However, it is higher than that found in the Islamic Republic of Iran (19.7%) (23), India (13.2%) (24), and Turkey (13.3%) (25). It is similar to the prevalence found in Jordan (24.4%) (26). Using the WHO reference cut-offs we found a prevalence of overweight of 28.3%. This prevalence is higher than that in Yemen (20.7%) (27) and Nigeria (13%) (28) but close to that in Saudi Arabia (28.7%) (29) and lower than that in Dubai (40.9%) (30).

^aThere is no cut-off for obesity in French reference.

In Algeria, representative nationwide studies on the prevalence of overweight and obese children are not yet available. Using IOTF reference, in Constantine, the prevalence of overweight in children 6–10 years was 9.5% in 2006 (3). In Tébessa (eastern Algeria), between 2005 and 2007, the reported prevalence was 8.5% (31). In Oran city (western Algeria), 13% of children aged 6–11 years were overweight (32), while, in Sidi-bel-Abbes (also western Algeria), in 2008, the prevalence of overweight using IOTF, French and CDC references in 8–15-year-old children was respectively 7.9%, 7.7% and 7.2% (15). In Constantine, using WHO reference cut-offs, the prevalence of overweight in 7–11-year-old children in 2013 was reported to be 26.4% (33).

The higher prevalence of overweight in our study might be explained by the recent trend of socio-economic transition coupled with the nutrition transition in Algeria. This prevalence of overweight is a challenge for public health interventions because overweight children are at a higher risk of noncommunicable and degenerative diseases in adulthood. It is not only the availability of and household access to food that determines the nutritional status of children. Factors such as education, sanitation, accessibility and quality of health services, and cultural attitudes and beliefs are equally important. In the area of Constantine, we showed in 2003 that watching television, time spent in sedentary activities and food quality were risk factors for overweight in a sample of schoolchildren aged 6 to 12 years (34). In the current sample, we also collected information on risk factors for overweight and found that overweight children did less sport, ate breakfast less often, and watched 2 hours more television than normal weight children (35). We also observed a link between parental and child obesity, and that the prevalence of overweight was more common

in children who were not exclusively breastfed whose mothers worked.

The differences in the prevalence of underweight and overweight using the different references can be explained by the setting different cut-offs used by the references, which can be influenced by factors such as time period, country of data source and design of the study. Thus, it is advisable to know the basis on which a reference cut-off was calculated before applying it to any population-based study.

Conclusion

The considerable prevalence of overweight and a persistent burden of underweight found in our sample suggests the existence of nutrition transition in Constantine. The prevalence of malnutrition differs depending on the reference used, which suggests international references should be used with care to avoid any potential misclassification of children. The differences obtained by using different cut-off points at the individual and population level need further research to answer questions as to whether certain cut-off points are linked or not with morbidity or mortality endpoints. No Algerian national standard or reference is available to define overweight or underweight in Algerian children. It may be that Algerian children have different growth characteristics from the populations that were selected to develop the international references. Thus local age-specific BMI references and cut-offs for children are needed that can provide accurate predictions of the risk of metabolic morbidity and disease burden throughout life.

Prévalence du surpoids et du déficit pondéral chez les écoliers de Constantine (Algérie) : comparaison de quatre valeurs de référence utilisées comme seuils pour l'indice de masse corporelle

Résumé

Contexte : L'Algérie connaît une période de transition nutritionnelle et une augmentation un surpoids chez l'enfant.

Objectifs : La présente étude visait à déterminer la prévalence du surpoids et du déficit pondéral chez les enfants âgés de 6 à 10 ans à Constantine (Algérie), au moyen de quatre valeurs internationales de référence utilisées comme seuils pour l'indice de masse corporelle (IMC).

Méthodes : Une étude transversale a été réalisée entre février et mai 2015 dans un échantillon de 509 écoliers âgés de 6 à 10 ans. Leur taille et leur poids ont été mesurés selon les recommandations de l'Organisation mondiale de la Santé (OMS). Les valeurs utilisées comme seuils pour l'IMC par l'OMS, le groupe spécial international sur l'obésité, les Centers for Disease Control and Prevention (CDC) et les valeurs de référence nationales françaises ont été employées pour classer l'échantillon selon les catégories « surpoids » et « déficit pondéral » en fonction de l'âge et du sexe. Le coefficient kappa a été utilisé pour évaluer la concordance entre les valeurs de référence.

Résultats : Sur la base des différentes valeurs de référence utilisées comme seuils, la prévalence du déficit pondéral chez les enfants était comprise entre 1,4 % et 8,8 %. La prévalence du surpoids variait de 22,8 % à 28,3 %. La valeur de référence utilisée comme seuil par l'OMS donnait une prévalence du surpoids considérablement plus élevée chez les garçons que chez les filles (32,55 % contre 24,0 %, $p = 0,03$). Les valeurs du coefficient kappa (entre 0,251 et 0,954) indiquaient une correspondance allant de bonne à excellente entre les références.

Conclusion : La prévalence du surpoids et du déficit pondéral diffère chez les enfants de Constantine selon la valeur de référence utilisée comme seuil, ce qui semble indiquer que les valeurs internationales de référence devraient être utilisées avec prudence afin d'éviter toute erreur de classification de l'état nutritionnel des enfants.

انتشار زيادة الوزن ونقص الوزن لدى طلاب المدارس في قسنطينة، الجزائر: مقارنة أربع نقاط فاصلة مرجعية لمنسب كتلة الجسم

حياة اولعامرة، وسيلة علام، فوزية تباري، عبد الناصر عقلي

الخلاصة

الخلفية: تشهد الجزائر تحولاً في أساليب التغذية وزيادة في الوزن بصورة متنامية بين الأطفال.

الأهداف: هدفت الدراسة إلى تحديد زيادة الوزن ونقص الوزن لدى الأطفال الذين تتراوح أعمارهم ما بين 6-10 سنوات في قسنطينة، الجزائر، وذلك باستخدام أربع نقاط فاصلة مرجعية لمنسب كتلة الجسم.

طرق البحث: أجريت دراسة شاملة لعدة قطاعات في الفترة بين فبراير/ شباط ومايو/ أيار 2015 وشملت عينة ضمت 509 من طلاب المدارس الذين تتراوح أعمارهم ما بين 6-10 سنوات. وقد قيس طول الأطفال ووزنهم وفقاً لتوصيات منظمة الصحة العالمية. وصُنفت العينة حسب نقص أو زيادة الوزن وفقاً للعمر ونوع الجنس، وذلك من خلال استخدام النقاط الفاصلة لمنسب كتلة الجسم الخاصة بمنظمة الصحة العالمية، وفريق العمل الدولي المعني بالبدانة، ومراكز الوقاية من الأمراض ومكافحتها، والمرجع الوطني الفرنسي. واستُخدم معامل كبا لتقييم التوافق بين النقاط الفاصلة المرجعية.

النتائج: استناداً إلى النقاط الفاصلة المختلفة، تباينت نسب انتشار نقص الوزن في الأطفال لتتراوح بين 1,4 % إلى 8,8 %. كذلك تباينت نسب انتشار زيادة الوزن لتتراوح بين 22,8 % و 28,3 %. وبيّنت النقاط الفاصلة لمنسب كتلة الجسم الخاص بمنظمة الصحة العالمية ارتفاع نسبة انتشار زيادة الوزن في الفتيات عن الفتيان ارتفاعاً كبيراً (32,55 % مقابل 24,0 %، القيمة الاحتمالية = 0,03). وأظهرت قيم معامل كبا (بين 0,251 إلى 0,954) توافقاً معقولاً أو ممتازاً بين المراجع.

الاستنتاجات: يختلف انتشار زيادة الوزن ونقص الوزن لدى أطفال قسنطينة حسب النقاط الفاصلة المرجعية المستخدمة، مما يشير إلى ضرورة استخدام المراجع الدولية مع الحرص على تجنب أي تصنيف خاطئ محتمل لحالة تغذية الأطفال.
